

Fermi surface renormalization in Hubbard ladders

Kim Louis, J.V. Alvarez, and Claudius Gros

Fakultät 7, Theoretische Physik, University of the Saarland, 66041 Saarbrücken, Germany.

We derive the one-loop renormalization equations for the shift in the Fermi-wavevectors for one-dimensional interacting models with four Fermi-points (two left and two right movers) and two Fermi velocities v_1 and v_2 . We find the shift to be proportional to $(v_1 - v_2)U^2$, where U is the Hubbard- U . Our results apply to the Hubbard ladder and to the $t_1 - t_2$ Hubbard model. The Fermi-sea with fewer particles tends to empty. The stability of a saddle point due to shifts of the Fermi-energy and the shift of the Fermi-wavevector at the Mott-Hubbard transition are discussed.

Introduction - Fermi-surface properties of one- and two- dimensional interacting electron systems are a fascinating topic of current interest, motivated in part by the opening of a pseudogap in underdoped cuprates. Several novel effects have been found in generalized renormalization-group (RG) approaches to weak coupling models, in particular the formation of quasiparticle gaps¹ and a Pomaranchuk² and charge³ instability in N -patch 2D-Hubbard models^{4,5}.

Novel Fermi-surface effects are possible also in N -band 1D-dimensional interacting models, e.g. N -leg ladders⁶. Interest in the field of ladders systems has grown rapidly in the last years due to the discovery of superconductivity in a doped two-leg ladder material^{7,8} and due to the fact that a rigorous weak-coupling analysis can be carried through.

There have been a number of previous RG investigations of 1D interacting two-band systems. Penc and Sólyom⁹ extended an earlier calculation of Varma and Zawadowski¹⁰ and studied the Fermi-velocity renormalization at two-loop. Fabrizio¹¹ considered the role of the transverse hopping t_p on the stability of the Luttinger-liquid (LL) state both for the case of particles with and without spin. Balents and Fisher¹² considered the same model we do, a general 1D model with four Fermi points. There are several phases with x gapless charge and y gapless spin modes (notation: $CxSy$) in the phase diagram which were identified by Balents and Fisher considering the bosonized form of the leading divergent running couplings. The new feature we wish to stress is that the general phase diagram is influenced by the RG-flow of the Fermi vectors, which we evaluate explicitly. This Fermi-surface effect is especially strong near a saddle point.

It is well known¹³ that the tadpole (or Hartree) diagram contributes to the renormalization of the quadratic part of the original Hamiltonian, thus leading to a renormalization of the chemical potential in the case of a one-band model. Alternatively, one might wish to work with

a constant density of particles. This can be achieved by the introduction of appropriate counter terms to the chemical potential¹³. Here we would like to point out, that the tadpole diagram leads, in general, to different quadratic terms, which we denote by μ_1 and μ_2 , for the two bands in a 1D two-band model, see Fig. 1. The renormalization of the chemical potential is given in the 2-band case by suitable average of μ_1 and μ_2 . The difference of the two quadratic terms results, on the other hand, in a renormalization of the interchain hopping t_p and thus alters the band structure.

RG-equations - We will consider for a start a general two-band model with a linearized one-particle spectrum around the Fermi-points k_1 and k_2 and denote with v_1 and v_2 the Fermi-velocities for the first band (L_1 and R_1) and second band (L_2 and R_2) respectively. Later on we will specify our results to the case of the Hubbard ladder and $t_1 - t_2$ Hubbard model. Since we will be working at one-loop, we will keep the Fermi-velocities constant throughout the calculation, even when the Fermi-points k_1 and k_2 are allowed to shift.

A list of possible coupling constants is given in Table I. The special couplings g_{2v} , g_w , g_{1v} and g_s exist only for the $t_1 - t_2$ Hubbard model. The couplings listed come in two flavors, namely for scattering between parallel and antiparallel spins ($\parallel$ and $\perp$) for backward scattering, $g_{\gamma 1j}$, and forward scattering, $g_{\gamma 2j}$, with $\gamma = 1, 2, x, t$ and $j = \parallel, \perp$. Back- and forward scattering amplitudes for parallel spins are not independent, we choose $g_{\gamma 1\parallel} \equiv 0$.

Spin-rotational invariance implies that the RG-flow leaves the combinations

$$g_{\gamma\rho} := -\frac{g_{\gamma 2\parallel} + g_{\gamma 2\perp}}{2}, \quad g_{\gamma\sigma} := 2g_{\gamma 1\perp} \quad (1)$$

invariant ($\gamma = 1, 2, x, t$), Here the index ρ and σ denote the charge and spin component respectively.

TABLE I. Coupling constants for (a) Umklapp and (b) normal scattering processes ($k_2 > k_1$ has been assumed). For the $t_1 - t_2$ Hubbard model one has to interchange $R_2 \leftrightarrow L_2$, compare Fig. (1) and (3).

label	condition	process ^(a)	label	process ^(b)
g_{2u}	$k_2 = \pi/2$	$L_2 L_2 \rightarrow R_2 R_2$	g_2	$L_2 R_2 \rightarrow L_2 R_2$
g_{2v}	$3k_2 + k_1 = 2\pi$	$L_2 L_2 \rightarrow R_1 R_2$	g_1	$L_1 R_1 \rightarrow L_1 R_1$
g_w	$3k_2 - k_1 = 2\pi$	$L_2 L_2 \rightarrow L_1 R_2$	g_x	$L_1 R_2 \rightarrow L_1 R_2$
g_{xu}	$k_2 + k_1 = \pi$	$L_2 L_2 \rightarrow R_1 R_1$	g_t	$L_2 R_2 \rightarrow L_1 R_1$
g_{tu}	$k_2 + k_1 = \pi$	$L_2 L_1 \rightarrow R_1 R_2$	g_s	$L_2 R_1 \rightarrow L_1 L_1$
g_{1v}	$k_2 + 3k_1 = 2\pi$	$L_2 L_1 \rightarrow R_1 R_1$		$(3k_1 = k_2)$
g_{1u}	$k_1 = \pi/2$	$R_1 R_1 \rightarrow L_1 L_1$		

The RG-equations to one-loop and momentum cut-off Λ are for general densities¹²

$$\begin{aligned} \dot{g}_{1\rho} &= \beta (g_{t\rho}^2 + \frac{3}{16}g_{t\sigma}^2) & \dot{g}_{1\sigma} &= -\alpha g_{1\sigma}^2 - \frac{\beta g_{t\sigma}^2}{2} + 2\beta g_{t\rho}g_{t\sigma} \\ \dot{g}_{2\rho} &= \alpha (g_{t\rho}^2 + \frac{3}{16}g_{t\sigma}^2) & \dot{g}_{2\sigma} &= -\beta g_{2\sigma}^2 - \frac{\alpha g_{t\sigma}^2}{2} + 2\alpha g_{t\rho}g_{t\sigma} \\ \dot{g}_{x\rho} &= -(g_{t\rho}^2 + \frac{3}{16}g_{t\sigma}^2) & \dot{g}_{x\sigma} &= -g_{x\sigma}^2 - \frac{1}{2}g_{t\sigma}^2 - 2g_{t\rho}g_{t\sigma} \\ \dot{g}_{t\rho} &= g_{0\rho}g_{t\rho} + \frac{3g_{0\sigma}g_{t\sigma}}{16} & \dot{g}_{t\sigma} &= g_{0\sigma}g_{t\sigma} + (g_{0\rho} - \frac{g_{0\sigma}}{2} - 2g_{x\sigma})g_{t\sigma}, \end{aligned}$$

where the coupling constants have been rescaled by $1/(\pi(v_1 + v_2))$, $t = -\ln(\Lambda/\Lambda_0)$ (Λ_0 is the initial cut-off) and where we have introduced

$$\alpha = \frac{v_1 + v_2}{2v_1}, \quad \beta = \frac{v_1 + v_2}{2v_2} \quad (2)$$

($1/\alpha + 1/\beta = 1$). The initial values of the rescaled coupling constants are

$$g_{\gamma\rho} = \frac{-U}{2\pi(v_1 + v_2)}, \quad g_{\gamma\sigma} = \frac{2U}{\pi(v_1 + v_2)} \quad (3)$$

for the Hubbard model. Inclusion of Umklapp scattering at special fillings leads to additional terms. They are

$$\begin{aligned} \dot{g}_{1\rho} &= \dots - \alpha g_{1u}^2 \\ \dot{g}_{1u} &= -4\alpha g_{1u}g_{1\rho} \end{aligned} \quad (4)$$

for g_{1u} , where the dots in the first equation denote the generic terms¹⁴. We find

$$\begin{aligned} \dot{g}_{t\rho} &= \dots + \frac{\alpha}{2}g_s^2, & \dot{g}_{t\sigma} &= \dots - 2\alpha g_s^2 \\ \dot{g}_s &= g_s \left(-2\alpha g_{1\rho} - 3g_{x\sigma}/4 + g_{x\rho} \right) \end{aligned} \quad (5)$$

for g_s and

$$\begin{aligned} \dot{g}_{t'\rho} &= \dots - \alpha g_{1v}^2, & \dot{g}_{1\rho} &= \dots - 2g_{1v}^2 \\ \dot{g}_{1v} &= g_{1v} \left(-2g_{t\rho} - 2g_{x\rho} - 2\alpha g_{1\rho} \right) \end{aligned} \quad (6)$$

for g_{1v} (with $\gamma' = x, t$). The RG-equations can be solved numerically, we present in Fig. 2 a typical flow diagram for some selected coupling constants.

Phase diagram - Above RG-equations can be easily implemented either for the Hubbard ladder or for the $t_1 - t_2$ Hubbard with respective dispersion relations

$$\begin{aligned} E_{\pm}^{(lad)}(k) &= \pm t_p - 2t \cos(k) \\ E^{(12)}(k) &= -2t_1 \cos(k) - 2t_2 \cos(2k). \end{aligned} \quad (7)$$

The reflection symmetry in the Hubbard ladder (exchange of the two legs) forbids any coupling with an odd number of operators per band, see Tables I and II.

In Fig. 3 we present the phase-diagram for the $t_1 - t_2$ Hubbard model, for which the control-parameter β takes the form

$$\beta = \frac{v_1 + v_2}{2v_2} = \frac{\sin(k_1) + \sin(k_2)}{2 \sin(k_2)}, \quad (8)$$

At half filling $k_2 - k_1 = \pi/2$. Depending on β , various coupling constants might scale to strong coupling, the divergence is in general of the form $\sim g^*/(t^* - t)$. In Table II a complete list of the diverging coupling constants is given. The differences between the Hubbard ladder and the $t_1 - t_2$ Hubbard model, which stem from the different geometries of the two Fermi-seas, are pointed out in Table II.

The Umklapp scattering g_{2u} at $k_2 = \pi/2$ is not active in the $t_1 - t_2$ Hubbard model, since $k_2 > \pi/2$ for this model. g_{2v} is allowed in the $t_1 - t_2$ Hubbard model and would lead to a C1S0 phase if (a) $3k_2 + k_1 = 2\pi$ and (b) $\beta > 2.4$. It turns out, that it is not possible to satisfy both conditions at the same time. Inspecting the fix-point Hamiltonian and bosonizing the diverging coupling constants¹², see Table II, one finds that the number of gapless charge and spin modes are C1S2 (1u,2u), C1S0 (1v,2v), C1S1 (s,w) and C0S0 (xu,tu).

RG of Fermi-wavevectors - The renormalization equations for the local chemical potentials are given by the tadpole diagram:

$$\dot{\mu}_i = \Lambda(v_1 + v_2)(g_{i\rho} + g_{x\rho}), \quad (i = 1, 2). \quad (9)$$

Note that the cut-off Λ occurs on the right-hand side of Eq. (9) and that the $\dot{\mu}_i$ are linear in the coupling constants. Let's consider now a renormalization step, we write

$$\Delta\mu_i = \Delta\mu_i^0 + \Delta\mu_{ct}, \quad (10)$$

where the counter-term $\Delta\mu_{ct}$ is introduced in order to enforce particle number conservation.

TABLE II. Diverging coupling constants in all possible phases, $\kappa = \max(\alpha, \beta)$.

phase	conditions	divergent couplings	
		$\rightarrow (-\infty)$	$\rightarrow (+\infty)$
C2S2	$\kappa > 4.8$	(none)	(none)
C2S1	$4.8 > \beta > 4.3$	$g_{1\sigma}$	(none)
C2S1	$4.8 > \alpha > 4.3$	$g_{2\sigma}$	(none)
C1S0	$4.3 > \kappa$	$g_{t\rho}, g_{x\rho}, g_{1,2\sigma}$	$g_{t\sigma}, g_{1,2\rho}, (g_{x\sigma})^\ddagger$
1u		$g_{1\rho}$	g_{1u}
2u [†]		$g_{2\rho}$	g_{2u}
1v*, 2v* [†]	$\kappa > 2.4$	$g_{t\rho}, g_{x\rho}, g_{1,2\sigma}$	$g_{t\sigma}, g_{1,2\rho}, g_{x\sigma}$
s*		$g_{x\rho}, g_{1\rho}, g_{t\rho}$	$g_s, g_{2\rho}$
w*		$g_{x\rho}, g_{2\rho}, g_{t\rho}$	$g_w, g_{1\rho}$
xu [†] , tu [†]		$g_{t\rho}$	$g_{xu}, g_{tu\sigma}$
		$g_{t\rho}, g_{x\rho}, g_{1,2\sigma}$	$g_{t\sigma}, g_{1,2\rho}, g_{x\sigma}$

*Does not occur in the ladder due to transversal momentum conservation.

† Does not occur in the $t_1 - t_2$ model due to conditions on k_1 and k_2 .

‡ Subleading divergence $\sim g_{x\sigma}^*/\sqrt{t^* - t}$.

The counter term is compensated by subtracting the corresponding term from the interaction part of the Hamiltonian. The size of $\Delta\mu_{ct}$ is determined for the Hubbard ladder by the condition ($\Delta k_i v_i = \Delta\mu_i^0$)

$$\Delta k_1 = -\Delta k_2, \quad v_2 \Delta\mu_1^0 = -v_1 \Delta\mu_2^0 \quad (11)$$

(for the $t_1 - t_2$ Hubbard model $\Delta k_1 = \Delta k_2$ etc.), which leads to

$$\begin{aligned} \Delta\mu_i^0 &= (-1)^i \frac{v_i}{v_1+v_2} (\Delta\mu_2 - \Delta\mu_1) \\ \Delta\mu_{ct} &= \frac{v_1}{v_1+v_2} \Delta\mu_2 + \frac{v_2}{v_1+v_2} \Delta\mu_1. \end{aligned} \quad (12)$$

Eq. (12) and Eq. (9) lead then to

$$\dot{k}_i = (-1)^i \Lambda (g_{2\rho} - g_{1\rho}), \quad (13)$$

which describes the flow of the Fermi-wavevector. Since the initial values for $g_{1\rho}$ and $g_{2\rho}$ are identical, see Eq. (3), a non-trivial renormalization of the Fermi-wavevector occurs only when $v_1 \neq v_2$, i.e. when $\alpha \neq \beta$. For the Luttinger-liquid phase C2S2 the limit

$$\Delta k_i = \lim_{t \rightarrow \infty} \int_0^t dt' \dot{k}_i(t') \quad (14)$$

is well defined. In the other phases there is normally a plateau in $\Delta k_i(t) = \int_0^t dt' \dot{k}_i(t')$, due to the decreasing cut-off Λ in the expression (13) for $\dot{k}_i$ which can be considered to define an approximate Δk_i , see Fig. 2.

Let us consider the flow of the Fermi-wavevector in some more detail for the Hubbard ladder, where $k_1 < k_2$ and $v_1 < v_2$. The relation $\alpha > \beta$ then leads generally to $g_{2\rho} > g_{1\rho}$ and consequently to

$$\Delta k_1 < 0, \quad \Delta k_2 > 0. \quad (15)$$

The smaller Fermi-sea tends to empty.

In the limit $U \rightarrow 0$ the renormalization of the coupling constants tends to zero in the C2S2 phase, and one can obtain an asymptotic rigorous expression for the total shift $\Delta k = -\Delta k_1$ using ($i = 1, 2$)

$$g_{i\rho}(t) \approx g_{i\rho}(0) + \dot{g}_{i\rho}(0) t, \quad \dot{g}_{i\rho}(0) = \frac{U^2/2}{v_1 + v_2} \frac{1}{\pi^2 v_{3-i}}$$

and Eq. (3) for $g_{i\rho}(0)$. With (13) and (14) we obtain

$$\begin{aligned} \Delta k &\approx \frac{\Lambda_0 U^2/2}{\pi^2 (v_1 + v_2)} \left(\frac{1}{v_1} - \frac{1}{v_2} \right) \\ &= \frac{U^2}{\pi^2} \frac{\alpha - \beta}{(v_1 + v_2)^2} \Lambda_0. \end{aligned} \quad (16)$$

The Fermi-surface renormalization effects become especially strong near a saddle point, where $v_1 \ll v_2$, i.e. $\alpha \gg \beta$. Eq. (16) has been derived for the case of the Hubbard ladder. For the $t_1 - t_2$ Hubbard model one has just to interchange $\alpha \leftrightarrow \beta$, both Fermi-points shift then

in the same direction (to larger values), see the inset of Fig. 3.

Discussion - In above discussion of the Fermi-surface renormalization we have kept the Fermi-velocities v_1 and v_2 . At two-loop, the Fermi-velocities are renormalized, an effect $O(U^3)$. The change of δk is, on the other hand, quadratic in U and leads therefore (for the ladder) to an additional reduction in v_1 , which is $O(U^2)$. This reduction in v_1/v_2 would lead to a further enhancement of Δk in a self-consistent treatment. We do not, however, expand this point here further, since it would involve a somewhat uncontrolled mixture of high- and low-energy scales.

It is of interest, however, to study the stability of the saddlepoint itself. This question has been studied extensively for the case of N -patch models of the 2D Hubbard model. Honerkamp *et al.*¹ have found, that particles tend to leave the saddle-point region (also called ‘hot spots’), in accordance to our result Eq. (16). Gonzalez *et al.*^{3,15} have found that the saddle point attracts the Fermi-level both from above and from below.

We have therefore considered the case when the Fermi-level is exactly at the bottom of the first band in the Hubbard ladder. In this case the usual RG-approach has to be modified. We have followed the approach proposed by Balents and Fisher¹² (an expansion in the curvature) and find with $v_1 = 0$

$$\dot{\mu}_1 = \Lambda v_2 g_{x\rho} \quad \dot{\mu}_2 = \Lambda v_2 g_{2\rho}. \quad (17)$$

As the initial values of $g_{x\rho}$ and $g_{2\rho}$ are identical for the Hubbard model, see Eq. (3), one has to consider the flow of $g_{x\rho}$ and $g_{2\rho}$, which is, due to the lack of scale-invariance, explicitly cut-off dependent. One finds¹⁶ $g_{2\rho} > g_{x\rho}$, i.e. the Fermi-level is pushed below the bottom of the first band. The saddle point is therefore pushed above the Fermi-level by the RG-flow.

Mott-Hubbard transition - A Mott-Hubbard transition occurs in the half-filled one-dimensional $t_1 - t_2$ model as a function of interaction strength U . For $t_2 > t_1/2$, that is for the case of four Fermi-points, this transition occurs at finite values of U . Aebischer *et al.* estimated¹⁷ a critical $U_c \sim 2.67 t_1$ for $t_2 = 0.7 t_1$. The question we would like to ask now is: How large is the Fermi-surface shift Δk for $U = U_c$? We cannot answer this question within our weak-coupling approach, but we can estimate the order of magnitude of Δk by assuming formula Eq. (16) to hold up to the Mott-Hubbard transition. We obtain

$$\Delta k|_{U=2.67 t_1}^{t_2=0.7 t_1} \approx 0.4 \Lambda_0 = 0.4 (\pi - k_2), \quad (18)$$

where we have taken $\pi - k_2$ as a physical relevant initial cut-off. This estimate indicates that the Fermi-wavevector is shifted by a substantial fraction towards the Brillouin zone edge near the Mott-Hubbard transition. We note that the real Δk might be even larger since we have neglected in this estimate the renormalization of

the Fermi-velocity which, as we have discussed further above, would enhance the effect. In principle it would be possible that the Mott-Hubbard transition coincides with $k_2 \rightarrow \pi$ for $U \rightarrow U_c$. Physically this would correspond to an activation of the one-band Umklapp scattering g_{1u} at the transition point.

Conclusions - We have derived and discussed the RG-equations for the Fermi-wavevectors in one-dimensional models with four Fermi-points. We find that the renormalization of the Fermi-wavevectors is quadratic in the interaction, suggesting substantial effects at strong coupling and near the Mott-Hubbard transition. We have pointed out, that the renormalization of the Fermi-wavevector is of especial importance near a saddle point, and that it leads to changes, Δv_i , in the Fermi-velocities quadratic in the coupling constant U , whereas the usual two-loop contributions to Δv_i are cubic in U .

In addition we have discussed the phase diagram of the 1D $t_1 - t_2$ Hubbard model and found a new phase (C1S1_{s/w}).

Acknowledgments - This work was partially supported by the DFG. One of us (C.G.) would like to thank W. Metzner for valuable discussions.

FIG. 1. Dispersion relation of a Hubbard ladder with interchain hopping t_p . The renormalization flow will lead, in general, to different “chemical potentials” for the two bands (a), which in turn will lead to renormalized Fermi-wavevectors (b). For the case of the Hubbard ladder, this process can be recast in a renormalization of the interladder hopping t_p .

FIG. 2. Example of the RG-flow of some selected coupling constants for the half-filled $t_1 - t_2$ Hubbard model with $U = 0.1t_1$, $t_2 = 0.7t_1$, $\alpha = 0.63$, $\beta = 2.4$ (C1S0 phase, see Fig. 3, corresponding to $k_1 = 0.418\pi$, $k_2 = 0.918\pi$ and $v_1 = 1.66t_1$, $v_2 = 0.43t_1$. The initial values of the coupling constants are given by Eq. (3). Also shown is the flow of the Fermi-surface shift Δk (in units of $\Lambda_0/100$).
